

Diffusion Model: Forward Noising + Reverse Denoising via U-Net (background)

In our simulation: each diffusion request runs reverse-process steps_default times (e.g. SDXL = 30), each step = a U-Net forward pass.

Legend: → forward: $q(x_t | x_{\{t-1\}})$ → reverse: $p_\theta(x_{\{t-1\}} | x_t)$ - - - → U-Net invocation
